Lights – General Data

1. General

The aircraft lighting system includes interior and exterior illumination. All lights operate from the aircraft 28 Volt DC power supply system. Individual circuits are protected by thermal push-pull circuit breakers and powered from a multiple bus network. (Refer to 24-30-00, DC Generation – General Data).

The landing lights are high intensity discharge (xenon) (Pre Mod 6/2285) or LED (Post Mod 6/2285). The wing inspection lights are incandescent (Pre Mod 6/2140). The majority of the other interior and exterior lighting is provided by LED (light emitting diode) lamps. All LED lamps are “high reliability” specification, which means that failure of a single LED in a lamp array will not result in failure of the lamp unit.

Pulse lighting capability is built into the landing light controller assembly. Aircraft equipped with optional TCAS I and TCAS II have a pulse light switch that enables manual or automatic (in response to a traffic advisory) activation of the pulse light system.

Controls for all instrument panel lighting are mounted on the control yoke, immediately forward of the reversion controller. There are two dimmers and one small toggle switch.
