Nose Gear – General Data

1. General

The nose gear consists of a non retractable, pneudraulic shock strut mounted on the forward face of the nose compartment bulkhead, and a single wheel supported on an axle within the fork of the shock strut. The shock strut is equipped with a hydraulically operated steering mechanism to steer the nose wheel. When the torque links are disconnected (as for towing) the nose wheel can be rotated 360°. A detachable cover is provided in the nose compartment to prevent loose objects obstructing the steering actuator, which is mounted on the shock strut.
